This kindÂ . z away from the first, shows that these individual knots have a compact set of values for z in which they are surrounded by the tail of the wave function. A second picture, computed from (\[logorder2\]) for $\Delta z\!=\!3$, shows a single knot surrounded by the tail of the wave function for this value of Δz. 5. We have found that the reconnection mechanism and the Arnold diffusion of the connected loops are driven by the nonlinear term $V(q)$. In particular, the amplitude of the reconnection process can be modulated by adjusting the parameters of the potential. In addition, there is a window of parameters for which the knot is created and evolves without getting dragged away by the reconnections, although the knot deformation is always quenched due to the collision and reconnection of the whole knot with the two sides of the domain. 6. When we used hyperbolic barriers, the parameter C in (\[pot\]) was related to a well depth. To have a similar dependence of the potential amplitude on a parameter C that is kept fixed in the simulation,

we chose a C that would be fixed if we were to modify the junction radius. Although both approaches give similar results for the wave function tail, they cannot be directly compared because a C fixed at infinity is not suitable for a shallow potential well. 7. The physical parameters for the quench were chosen to obtain the knot contraction in time shown in the paper. However, our results are valid for any quench with a low enough quench rate. For a larger quench rate, the knot is more likely to escape and it takes a larger value of C, i.e., $C_{\text{new}} > C_{\text{old}}$, to form a new knot. 8. Similar time evolution of the wave function can be found by exciting the system with the time independent Hamiltonian H_{0}. The motion of the knot is then decelerated due to the dissip
