Sentinel lymph node biopsy (SLNB) is considered to be a less accurate technique for staging than axillary lymph node dissection (ALND). We studied the utility of axillary metastases after SLNB as a prognostic factor in patients with breast cancer. A retrospective cohort study was conducted at a single tertiary care academic center. Patients with invasive breast cancer who underwent axillary lymph node dissection for assessment of axillary nodal status and had SLNB with/without confirmation of axillary nodal metastasis were identified. The Kaplan-Meier method was used to estimate time-to-event endpoints of axillary metastases, and a logistic regression model was used to analyze the risk factors of axillary metastasis after SLNB. We studied 305 patients. Of them, 164 had SLNB and/or ALND, of whom 94 (56.8%) had confirmed axillary nodal metastasis. For the remaining 141 patients, who had no confirmed axillary nodal metastasis, the rate of axillary metastases was 1.2% after SLNB, and the false negative rate was 8.0%. The rate of false negative rate for each subgroup according to the axillary nodal status is summarized in Table 4. The rate of axillary metastases after SLNB for patients without axillary nodal metastasis according to the clinicopathological factors was presented in Table 5. The independent factors associated with false negative rate were T4 status (OR, 24.8; 95% CI, 6.2-100.5; P
