Mammalian genes transferred via retroviral vectors predominantly express their transgene products within dividing cells that are actively producing messenger RNAs. Non-dividing cells, however, are often required in certain experimental situations. Thus, gene-transfer vectors and reporter gene constructs based on the CAG promoter, which is active only in dividing cells, are frequently used to study gene regulation and expression in cultured cells. The most effective vector for gene transfer into cultured cells is the amphotropic pseudotype derived from the Moloney murine leukemia virus. This vector replicates efficiently in dividing as well as non-dividing cells. In addition, some vectors exhibit CAG-promoter activity when introduced into myoblasts in vivo. It is, however, unclear whether or not the CAG promoter is activated in vivo by factors released from non-dividing cells. We have therefore analysed CAG-promoter mediated gene expression in transgenic mice. We demonstrate that the CAG promoter is active during osteogenesis in vivo as well as in vitro. We hypothesize that the CAG promoter might be activated by factors released from non-dividing cells. Impact of  $\beta(2)$ GPI on tissue factor-induced thrombin generation.  $\beta(2)$ -Glycoprotein I ( $\beta(2)$ GPI) may bind to tissue factor (TF) independently of its main receptor and result in increased thrombin generation. Little is known about the impact of  $\beta(2)$ GPI on thrombin generation in the presence of TF. Our objective was to evaluate the influence of  $\beta(2)$ GPI on thrombin generation in the presence of TF. Fibrin formation was assessed in whole blood in the presence or absence of  $\beta(2)$ GPI, using the calibrated automated thrombography (CAT) assay. The impact of  $\beta(2)$ GPI-dependent receptor activation was studied in the presence of TF-directed low molecular weight heparin (LMWH) and by active site inhibition of  $\beta(2)$ GPI. Thrombin generation was shortened and the maximum rate
